

Data Models, Coordinates, and Geometries

HES 505 Fall 2025: Session 7

Matt Williamson

Today's Plan

1. Ways to view the world
2. What makes data (geo)spatial?
3. Geometries, support, and spatial messiness

How do you view the world?

...As a Series of Objects?

- The world is a series of *entities* located in space.
- Usually distinguishable, discrete, and bounded
- Some spaces can hold multiple entities, others are empty
- Objects are digital representations of entities

...As a Continuous Field

Operationalizing views of space

What is a data model?

- **Data:** a collection of discrete values that describe phenomena
- Your brain stores millions of pieces of data
- Computers are not your brain
 - Need to organize data systematically
 - Be able to display and access efficiently
 - Need to be able to store and access repeatedly
- Data models solve this problem

2 Types of Spatial Data Models

- **Raster:** grid-cell tessellation of an area. Each raster describes the value of a single phenomenon. More next week...
- **Vector:** (many) attributes associated with locations defined by coordinates

The Vector Data Model

- **Vertices** (i.e., discrete x-y locations) define the shape of the vector
- The organization of those vertices define the *shape* of the vector
- General types: points, lines, polygons

(NEON)

Vectors in Action

- Useful for locations with discrete, well-defined boundaries
- Very precise (not necessarily accurate)

The Raster Data Model

- Raster data represent spatially continuous phenomena (NA is possible)
- Depict the alignment of data on a regular lattice (often a square)
- Geometry is implicit; the spatial extent and number of rows and columns define the cell size

Types of Raster Data

- **Regular**: constant cell size; axes aligned with Easting and Northing
- **Rotated**: constant cell size; axes not aligned with Easting and Northing
- **Sheared**: constant cell size; axes not parallel
- **Rectilinear**: cell size varies along a dimension
- **Curvilinear**: cell size and orientation dependent on the other dimension

Types of Raster Data

- **Continuous:** numeric data representing a measurement (e.g., elevation, precipitation)
- **Categorical:** integer data representing factors (e.g., land use, land cover)

What makes data (geo)spatial?

Location vs. Place

- **Place:** an area having unique **physical** and **human** characteristics **interconnected** with other places
- **Location:** the actual position on the earth's surface
- **Sense of Place:** the emotions someone attaches to an area based on experiences
- Place is *location plus meaning*
- **nominal:** (potentially contested) place names
- **absolute:** the physical location on the earth's surface

Describing Absolute Locations

- **Coordinates:** 2 or more measurements that specify location relative to a *reference system*
- Cartesian coordinate system
- *origin* (O) = the point at which both measurement systems intersect
- Adaptable to multiple dimensions (e.g. z for altitude)

Cartesian Coordinate System

Describing location: extent

- How much of the world does the data cover?
- For rasters, these are the corners of the lattice
- For vectors, we call this the bounding box

Describing location: resolution

- Resolution is the smallest distance between two points that can be distinguished
- Resolution is determined by the wavelength of the light used to observe the object
- Resolution is determined by the diameter of the aperture used to observe the object
- Resolution is determined by the quality of the optical system
- Resolution is determined by the quality of the detector
- Resolution is determined by the quality of the data processing
- Resolution is determined by the quality of the environment
- Resolution is determined by the quality of the observer
- Resolution is determined by the quality of the instrument
- Resolution is determined by the quality of the method
- Resolution is determined by the quality of the result
- Resolution is determined by the quality of the process
- Resolution is determined by the quality of the product
- Resolution is determined by the quality of the service
- Resolution is determined by the quality of the support
- Resolution is determined by the quality of the infrastructure
- Resolution is determined by the quality of the resources
- Resolution is determined by the quality of the personnel
- Resolution is determined by the quality of the equipment
- Resolution is determined by the quality of the materials
- Resolution is determined by the quality of the information
- Resolution is determined by the quality of the communication
- Resolution is determined by the quality of the organization
- Resolution is determined by the quality of the management
- Resolution is determined by the quality of the culture
- Resolution is determined by the quality of the values
- Resolution is determined by the quality of the beliefs
- Resolution is determined by the quality of the attitudes
- Resolution is determined by the quality of the behaviors
- Resolution is determined by the quality of the outcomes
- Resolution is determined by the quality of the impacts
- Resolution is determined by the quality of the contributions
- Resolution is determined by the quality of the legacies
- Resolution is determined by the quality of the futures
- Resolution is determined by the quality of the dreams
- Resolution is determined by the quality of the hopes
- Resolution is determined by the quality of the wishes
- Resolution is determined by the quality of the desires
- Resolution is determined by the quality of the needs
- Resolution is determined by the quality of the wants
- Resolution is determined by the quality of the requirements
- Resolution is determined by the quality of the expectations
- Resolution is determined by the quality of the standards
- Resolution is determined by the quality of the benchmarks
- Resolution is determined by the quality of the targets
- Resolution is determined by the quality of the goals
- Resolution is determined by the quality of the objectives
- Resolution is determined by the quality of the missions
- Resolution is determined by the quality of the visions
- Resolution is determined by the quality of the dreams
- Resolution is determined by the quality of the hopes
- Resolution is determined by the quality of the wishes
- Resolution is determined by the quality of the desires
- Resolution is determined by the quality of the needs
- Resolution is determined by the quality of the wants
- Resolution is determined by the quality of the requirements
- Resolution is determined by the quality of the expectations
- Resolution is determined by the quality of the standards
- Resolution is determined by the quality of the benchmarks
- Resolution is determined by the quality of the targets
- Resolution is determined by the quality of the goals
- Resolution is determined by the quality of the objectives
- Resolution is determined by the quality of the missions
- Resolution is determined by the quality of the visions

- **Resolution:** the accuracy that the location and shape of a map's features can be depicted
- **Minimum Mapping Unit:** The minimum size and dimensions that can be reliably represented at a given *map scale*.
- Map scale vs. scale of analysis

Geometries and Support

Geometries

- Vectors aggregate the locations of a feature into a geometry
- Most vector operations require simple, valid geometries

POINTS: Individual x, y locations.

ex: Center point of plot locations, tower locations, sampling locations.

LINES: Composed of many (at least 2) vertices, or points, that are connected.

ex: Roads and streams.

POLYGONS: 3 or more vertices that are connected and **closed**.

ex: Building boundaries and lakes.

neon

Image Source: Colin Williams (NEON)

Valid Geometries

- A **linestring** is *simple* if it does not intersect
- Valid polygons
- Are closed (i.e., the last vertex equals the first)
- Have holes (inner rings) that inside the the exterior boundary
- Have holes that touch the exterior at no more than one vertex (they don't extend across a line) - For multipolygons, adjacent polygons touch only at points
- Do not repeat their own path

Empty Geometries

- Empty geometries arise when an operation produces **NULL** outcomes (like looking for the intersection between two non-intersecting polygons)
- **sf** allows empty geometries to make sure that information about the data type is retained
- Similar to a **data.frame** with no rows or a **list** with **NULL** values
- Most vector operations require simple, valid geometries

Support

Support is the area to which an attribute applies.

For vectors, the attribute-geometry-relationship can be:

- **constant** = applies to every point in the geometry (lines and polygons are just lots of points)
- **identity** = a value unique to a geometry
- **aggregate** = a single value that integrates data across the geometry

Support

Support is the area to which an attribute applies.

For rasters:

- **point** = attribute refers to the cell center
- **cell** = attribute refers to an area similar to the pixel

Take Homes

- Data models translate views of space *into* analytic tools
- Spatial data requires **location**
- We store location in geometries
- We assign attributes to location based on support
